# Report of the workshop "Re-use potential of research data" of the German Network for Educational Research Data (VerbundFDB)

Report on the workshop of the VerbundFDB at the Institute for Educational Quality Improvement (Insitut zur Qualitätsentwicklung im Bildungswesen), Frankfurt, 19 June 2018

INTRODUCTION .....	1
FIRST PART: INPUT LECTURES AND DISCUSSION .....	1
SECOND PART: DEVELOPMENT OF CRITERIA FOR SUBSEQUENTE USE .....	2
ATENDEES .....	8
ANNEX .....	9

## Introduction

---

On June 19<sup>th</sup>, 2018, a workshop on the topic "Re-use potential of research data" was held at the Institute for Educational Quality Improvement, which was organized within the German Network for Educational Research Data (Verbund Forschungsdaten Bildung, VerbundFDB). Participants were ten researchers from different disciplines of empirical educational research. Representatives from the educational sciences, psychology, economics and sociology were present.

The aim of the workshop was to develop and discuss quality criteria for research data from the perspective of secondary users of research data.

## First part: Input lectures and discussion

---

### Input lectures

In the morning, Malte Jansen and Claudia Neuendorf gave an introduction to the topic. This included 1) reasons for the need of an appraisal of research data, 2) the description of the selection process, 3) previous approaches to the appraisal of research data and the assessment of the potential for re-use.

The reasons why the evaluation of research data is necessary were explained: With an increasing amount of data available and the need to invest resources wisely, an assessment should be made at an early stage as to whether research data is suitable for subsequent use by a larger community and whether the effort of comprehensive documentation and preparation is justified. Furthermore, the process of data selection and evaluation was discussed. Research data centers typically apply a multi-stage selection process in which the fit of the data with the collection guidelines of the respective research data center (RDC) as well as its archivability (with regard to technical, legal and documentary requirements) are evaluated. If these criteria are met, an assessment of the potential for subsequent re-use is also carried out, which leads to a decision on the investment of resources for data publication.

A process that is consistent, comprehensible, transparent and efficient is desirable. This process must be clearly defined and documented and it must be based on clearly formulated and operationalizable

selection and evaluation criteria. Standards already exist for the formal-technical criteria. However, criteria for evaluating the re-use potential from a content-based perspective are yet to be developed. Sometimes it is even doubted whether it is at all possible to name criteria for the appraisal of research data. Also, the question of who should be responsible for this evaluation has not yet been answered. The consensus is that in any case the scientific community should be involved - both in the definition of criteria for data re-use potential and in the development of an appraisal process.

Finally, some preliminary work on the evaluation of the re-use potential was presented: Results of a user survey, the preceding short expert survey, and, as an example, some criteria that IQB uses as a basis for prioritizing data processing.

### **Discussion**

In the ensuing discussion, it was suggested that the current secondary use of research data should be analyzed in order to empirically determine characteristics of widely used data sets. The GESIS data archive, for example, offers possibilities for such analyses. This presupposes, however, that operationalizable criteria already exist. It was pointed out, however, that such an empirical approach can only ever refer to the past, but that this does not cover the prediction of a future scientific interest in data sets.

Furthermore, the question was discussed as to who should assess the potential for the subsequent use of research data. The tendency was that scientists collecting the data themselves should make the assessment, for example in the project proposal.

Furthermore, it was discussed whether a high number of subsequent uses should be the goal of data provision - even data sets that have only been re-used in one study can be important for a research field.

It was important for the participants to emphasize that high-quality data sets that were generated with public funds in the past should be made available for re- use in order to grant all researchers fair and free access to these data. In this context, the datasets TIMSS transition, BIJU and ELEMENT-8 were mentioned as examples. Likewise, it should be easier to access data from the German national comparison tests (VERA-3 or VERA-8) for scientific purposes.

During the discussion, it already became clear that different criteria are used for judging the quality of data sets: For example, representative time series with frequent measurements were particularly interesting for sociologists in Germany (e.g. data from comparison tests). Sample sizes of less than 1000 were not considered re-usable. Other participants disagreed and said that even smaller sample sizes of high-quality studies can be interesting for some research questions.

### **Second part: development of criteria for subsequent use**

---

In the second part, the participants were asked in a brainstorming session to name aspects that come to their minds when assessing the quality of research data. For this purpose, the categories 1) preparation, 2) documentation, 3) content and 4) methodology were specified.

The workshop participants were then divided into three groups, with each group representing a different area of expertise: educational science, psychology and sociology/economy. The groups had one hour to

discuss aspects related to their field of expertise for assessing the quality of research data, collect their points on posters and, if possible, arrange them according to importance.

Afterwards, the results of the group work were discussed in a poster session. Some of the topics were mentioned for several disciplines; these will be assigned and summarized accordingly in the following. The poster illustrations are in the appendix.

### Documentation

The participants agreed that a **short summary** or a data manual is necessary, in which core information (sample, study design (e.g. sampling, survey details) and topics/contents) of the study are clearly presented.

**Codebooks or scale documentation** are considered important. As minimum information for each scale 1) the name and a short description of the construct, 2) the source of the scale and 3) the item wordings are named.

This means that the items must be assigned to a scale. Also inversions of items and other re-codings that have already been made must be indicated. Additional information that often appears in the scale documentation is the number of cases, information about missings, mean values and internal consistencies. However, information that researchers themselves can calculate from the data is not absolutely necessary in the eyes of the researchers. The format of the documentation (whether Excel, Word or in SPSS labels) is not decisive.

Documentation also includes that the naming of scales in the data set or the scale manual is theory-based and, if possible, uniform across studies. However, this is seen as a challenge, since there are nuanced differences in the meaning of certain constructs depending on their theoretical provenance (e.g. cognitive activation according to Klieme vs. Seidel). However, an entry or cross-referencing in the "Database on School Quality"<sup>1</sup> could help here. The social science item and scale compilation<sup>2</sup> and PSYNEX tests<sup>3</sup> also provide information about scales and tests that could be referenced in the documentation.

In addition, the **original questionnaires** are considered important.

Both scale documentation and original questionnaires pose a challenge for the documentation if they are protected by copyright law.

It would also be desirable to have a **file documenting potential pitfalls** or FAQs for each dataset, pointing out special features of the dataset (e.g. special features in linking student and teacher data, high rates of attrition, other **anomalies** and unusual features that primary researchers or other users may have encountered during preparation and evaluation).

<sup>1</sup> DaQS (<https://daqs.fachportal-paedagogik.de>)

<sup>2</sup> ZIS (<https://zis.gesis.org>)

<sup>3</sup> <https://www.psyndex.de/index.php?wahl=PSYNEXTests>

**Uniform documentation (with regard to the information contained and the format)** across studies would facilitate subsequent use (e.g. through automated routines at the RDC).

On several occasions, good **keywording** of the studies was called for in order to improve the retrieval of relevant data sets. However, a mapping of the terms searched for in different disciplines would be important (in this case, techniques and expertise for keywording from library and information sciences should be used).

It would be helpful if an RDC offered a **description of the depth of documentation** on the study website so that researchers would know transparently what to expect when applying for the study.

### **Preparation**

In the discussions, it became clear that documentation and preparation are closely related, since data preparation is carried out partly for documentation purposes and, conversely, the documentation of the processing steps themselves is also important.

In the case of preparation, the researchers demand

- consistent logic in the naming of variables
- a uniform documentation of missing values
- information on the nested data structure (school ID, class ID, student ID)

A major point of discussion was the question in which processing state data sets should be delivered. Basic data cleansing should already have taken place. Apart from this, however, the scientists would like to see both raw data and already processed data (e.g. indicators already formed (e.g. HISEI, class membership), scaled data, possibly imputed data) or a corresponding processing syntax. This would improve the traceability of the processing, provide maximum flexibility for secondary researchers and at the same time save time-consuming and error-prone recoding.

In the case of longitudinal studies, it is also desirable to have a uniform designation of waves as well as to indicate the participation status and new additions to the data.

Finally, providing a well usable file format including a syntax for importing the data into different statistical programs is desirable.

More important than the question of good formatting, however, is that the data is available at all.

### **Data access**

An additional point raised by researchers is data access. On the one hand, this concerned differences in **data protection standards** between data centers. Some researchers would like to see a more **uniform approach** here. The tension between data protection and Open Data for the scientific community was perceived and the scientists would like the RDC to champion the interests of data users.

Further, **low-threshold, free** access to data was important to the researchers. If remote computing is the only option, online access, such as remote desktop, should be used instead of the JosuA portal, which leads to time delays.

## Contents of the data

Regarding data content, there were numerous requests to improve data quality. Researchers would like to have a high data density: as many 1) measurement points, 2) study participants, 3) variables and 4) instruments as possible.

With regard to variables and instruments, there was consensus on some points, but there were also differences between the different subject-fields. For example, everyone wanted comprehensive background information on the study participants (see illustrations). Here, it is important that the constructs are recorded in a standardized way so that different studies can be related to each other in terms of content and, for example, trend analyses can be carried out. This also applies to different waves of a longitudinal study. There were also participants who went even further and referred to the examples of different countries and states in which it is possible to obtain very detailed information from official statistics for scientific purposes (e.g. school entrance examinations, VERA data, "core data set", social security numbers). To this end, the researchers would like to see closer cooperation between the RDC and the authorities.

For the participating social scientists, the topic of regional information was particularly important. This information makes it possible to investigate research questions on school transitions, effects of streaming, teaching and educational reforms. Also, by providing regional information that is as detailed as possible, the combination of datasets with external information becomes feasible. Examples of regional information are very rough subdivisions (such as city-country), information that allow the comparison of different educational systems within the Federal Republic of Germany (e.g. federal states), or very small-scale subdivisions (such as district and municipal level). One way to make this possible while maintaining data protection would be routines that allow external information (e.g. from official school statistics<sup>4</sup>) on the school location to be linked to the data set via syntaxes, without the regional identifier itself having to be issued by data centers.

Psychologists and educational scientists also wanted to see the presence of cognitive, psychosocial, emotional and motivational constructs as well as information on teaching quality and teaching processes. In this context, the use of scales with multiple indicators (items) was preferable to the use of single item scales.

A discussion arose on the question of whether classic scales (e.g. test anxiety) or innovative scales (e.g. use of digital media) have a greater potential for subsequent use. Ultimately, there was agreement that originality and connectivity (to international research, e.g. use of established constructs that are recorded relatively similarly in different studies) should be balanced.

## Methodology

The density of data also plays a role in the methodology of the study: **longitudinal studies** are particularly well suited for re-use, especially longitudinal studies at individual level (panel surveys). The continuity and comparability of the survey over time (same operationalization/recording of constructs) is of particular importance. Examples of large, longitudinal studies in Germany are NEPS and SOEP, where the

---

<sup>4</sup> Their availability could still be improved.

researchers stress the importance to the connection to the scientific community, which is guaranteed by the structure of these two panel studies. Potential is also seen for longitudinal links in school achievement studies: for example, between students participating in IQB Trends in Student Achievement both in primary and secondary school, in the sampling of a school panel in the IQB Trends in Student Achievement, or in establishing links between the IQB Trends in Student Achievement and NEPS. The publication of PISA-I-Plus-2012/2013 data is also highly anticipated by the scientific community. In this context, the question of whether a data set allows causal inferences was also mentioned as a criterion. In the eyes of some, however, this was a rather difficult criterion, since disciplines also differ in their understanding of causal inference.

Indicators related to the **sample** were mentioned as criteria of data quality: the size of the sample, its representativeness (elaborate sampling) and a high sampling rate. With regard to representativeness, however, there were also voices who felt that this aspect was not so important.

One aspect of the methodology of a study that considerably improves the potential for re-use is the **combination of different survey instruments** (tests, questionnaires, observations, etc.) and **different observers** (e.g. teachers, pupils, parents, etc.).

The question of whether experimental studies would in principle have a lower potential for subsequent use tended to be answered negatively. On the one hand, many experimental studies focus on a very specific issue, so that their analysis potential is often already exhausted during primary use, but on the other hand, the potential for re-use could be improved if the experimental design was combined with questionnaires enriched with standard indicators. There are examples of large experimental field studies with a high potential for re-use (e.g. on teaching methods: IGEL study at the DIPF).

#### **Further discussion themes**

One criterion was that a data set should enable high-ranking publications, and the question arose how this could be predicted.

When asked about other easily operationalizable criteria (such as the size of the consortium, interdisciplinarity, funding amount), the researchers felt that these had a rather small influence on the potential for re-use.

The researchers also discussed that the potential for re-use should not be confused with the importance of the study. There are many small-scale studies that are very important, but not very suitable for re-use.

Different aspects were discussed with regard to the question of whether **actuality** is an important criterion. While, on the one hand, a study using older data is often accused in the review process that the results may already be outdated due to the age of the data and the change in the educational context, historical data, on the other hand, allow comparisons over time. It is therefore worthwhile to prepare and provide both current and older data sets (e.g. FIMSS, Fend's studies). It would be ideal if earlier studies could be linked to current data, e.g. by building on old studies to continue them.

The researchers agreed that there is historical data that is of great value as a basis for an entire research area, but that have never been made available to the scientific community for re- and secondary analysis. It was argued in the discussion that these data were also collected with taxpayers' money and therefore

should not be regarded private property by those who collected them. In the interests of fairness, transparency and good scientific practice, efforts should be made to prepare and make these data available.

While data sets from some projects are known to scientists (e.g. LIFE-Study (Fend), SCHOLASTIK incl. the highly gifted add-on by Heller, PALMA, TOSCA, BIJU, PISA-Plus), it can be assumed that further data sets still exist, but these are, for example, held by emeritus professors or on servers to which hardly anyone has access. There is a desire that the entire community be called upon to raise such old "data treasures" and to invest resources, prepare them and make them available.

## Atendees

---

### Experts

Dr. Katrin Arens (DIPF, Frankfurt a. M.)

Dr. Gwendolin Blossfeld (University of Bamberg)

Prof. Katja Görlitz (German Institute for Economic Research (DIW), Berlin and FU Berlin)

Prof. Marcel Helbig (University of Erfurt, Social Science Research Center Berlin (WZB))

Dr. Lydia Kleine (Leibniz Institute for Educational Pathways (LifBi), Bamberg)

Dr. Susanne Kuger (German Youth Institute (DJI), Munich)

Prof. Rebecca Lazarides (University of Potsdam)

Prof. Martin Neugebauer (FU Berlin)

Dr. Rolf Strietholt (TU Dortmund University)

Dr. Sebastian Wurster (Johannes Gutenberg University Mainz)

### IQB Staff

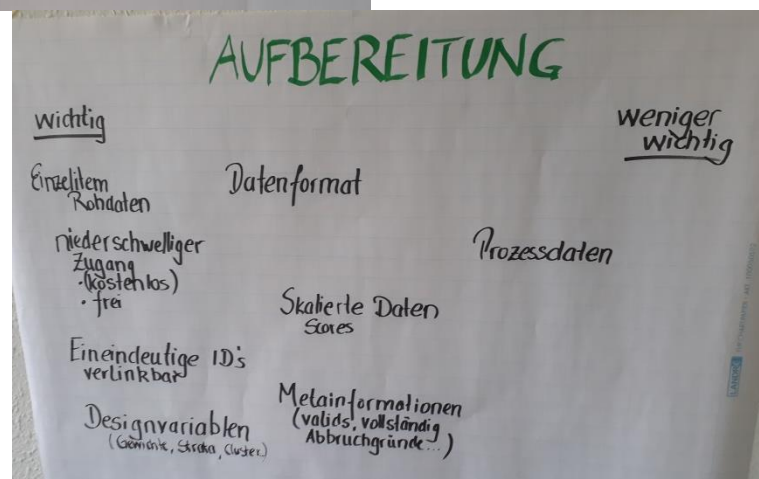

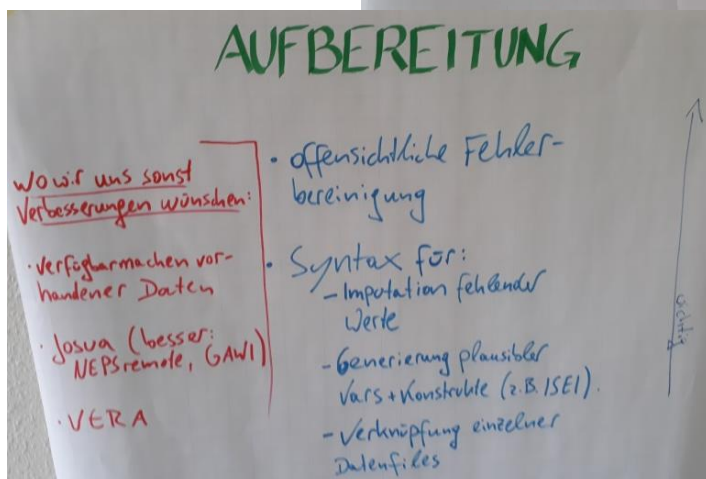

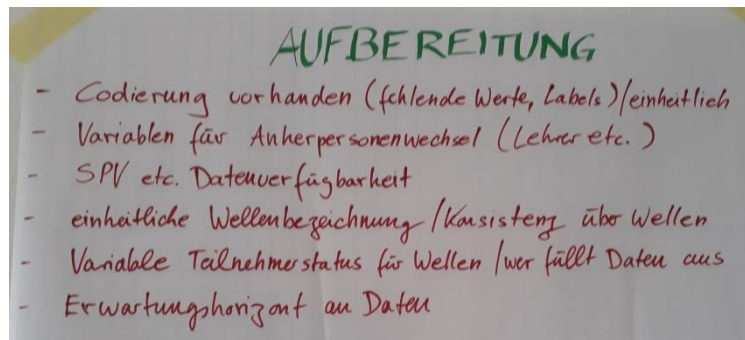

Dr. Malte Jansen (Head of Research Data Center at the Institute for Educational Quality Improvement (FDZ at IQB))

Claudia Neuendorf (research associate, German Network for Educational Research Data)

## Annex

The following is an overview of the posters developed by the participants on the four topics preparation, documentation, content and methodology. The poster in the upper row was created by the group of psychologists, the poster from sociology/economy is on the lower left and the results from educational science are shown on the lower right.

### Poster on the topic of preparation

#### Poster 1:

- Coding available (missing values, labels)/uniform
- Variable for change of personnel (teachers etc.)
- SPV etc. Data availability
- Uniform designation/consistency across waves
- Variable "participant status for waves" / who fills in data
- Expectation horizon for data

#### Poster 2 (left side):

- obvious fixes and data cleaning
- syntax for

- imputation of missing values
- generation of plausible variables and constructions (e.g. ISEI)
- Linking of individual data files

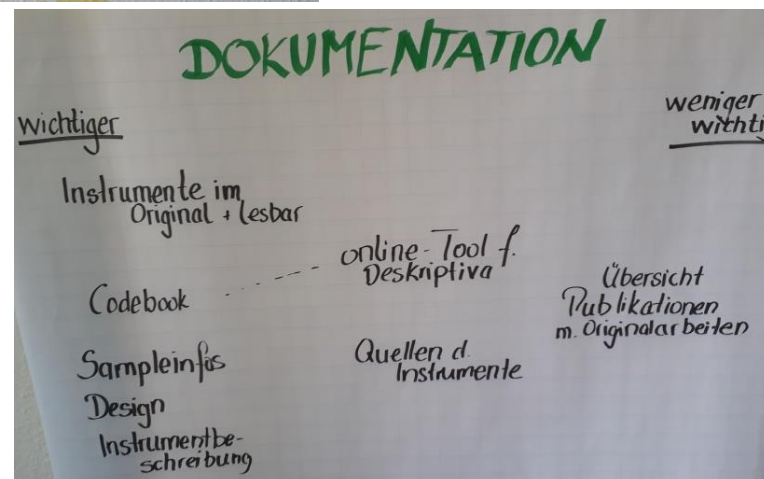

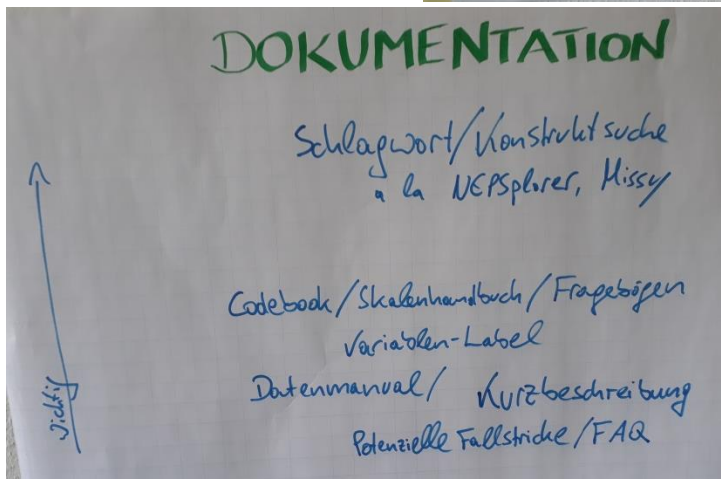

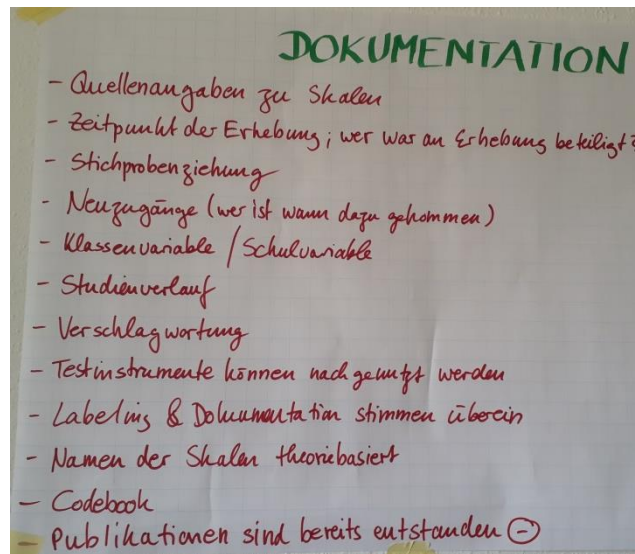

Where we would otherwise wish for improvements:

- Making existing data available
- Joshua (Better: NEPSremote, GAWI)
- VERA

**Poster 3** (right side, top is most important, bottom least):

- single item raw data
- low-threshold access (free, open access)
- unique IDs, linkable
- Design variables (weights, strata, clusters ...)
  
- scaled scores
- meta-information (valid, complete reasons for termination...)
  
- process data

## Poster on the topic of documentation

### Poster 1:

- Source information on scales
- Time of the survey; who was involved in the survey?
- Sampling
- Information on refresher samples (who has joined when)
- Class variable/school variable
- Course of studies
- Keywording
- Test instruments can be reused
- Labeling & documentation match
- Names of the scales theory-based
- Codebook
- Publications have already been produced

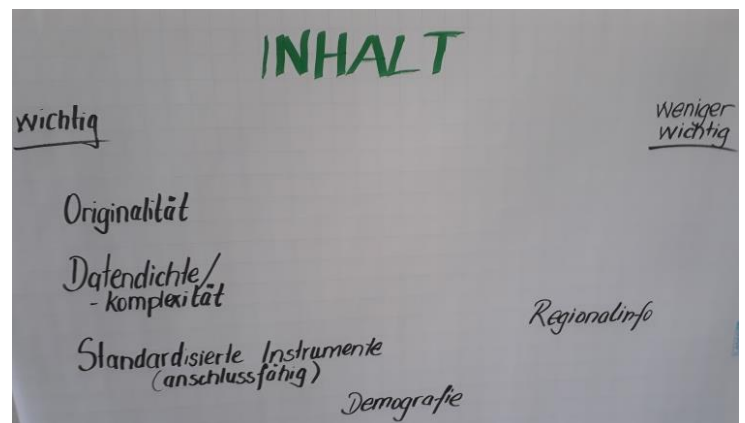

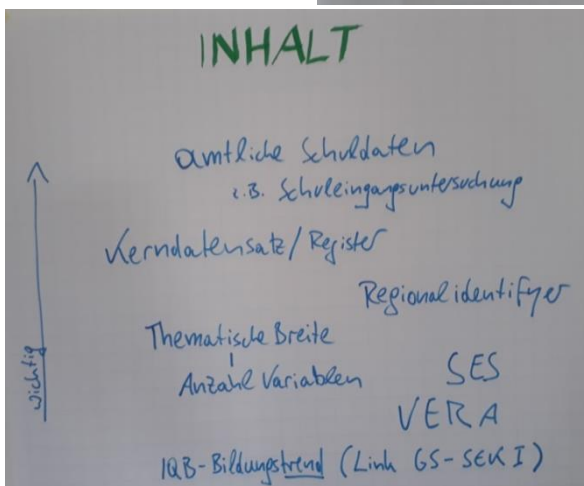

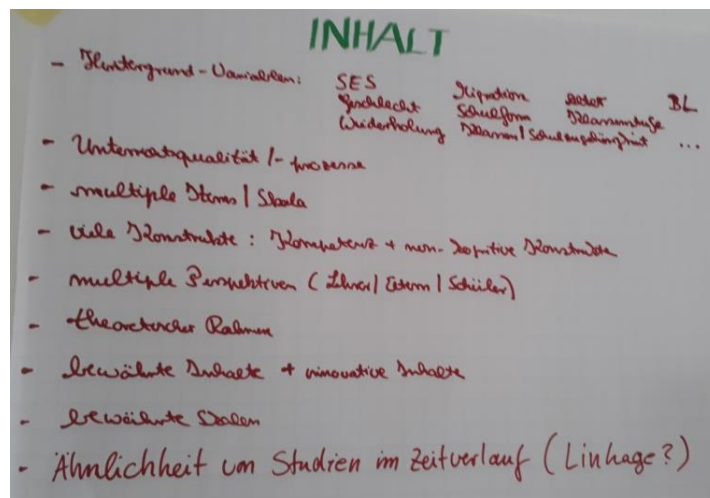

**Poster 2** (left side, top is most important, bottom least):

- Keyword/construct search a la NEPSplorer, Missy
- Codebook/scale handbook/questionnaires/variable label
- Data manual/short description/potential fall lines/FAQ

**Poster 3** (right side, top is most important, bottom least):

- Original instruments + readable
- Codebook --- online tool for descriptives
- Sample information
- Design
- Instrument description
- Sources of the instruments
- Overview of publications with original works

Poster on the topic of contents

Poster 1:

- Background variables: SES, Migration, Federal State, Repetition, Type of School, Grade Level, Gender, Classes/School Affiliation ...
- Teaching quality/processes
- Multiple Items/Scale
- Many constructs: Competence + non-cognitive constructs
- Multiple perspectives (teachers/parents/students)
- Theoretical framework
- Proven content + innovative content
- Proven scales
- Similarity around studies over time (Linkage?)

Poster 2 (left side, top is most important, bottom least):

- Official school data (e.g. school entrance examination)

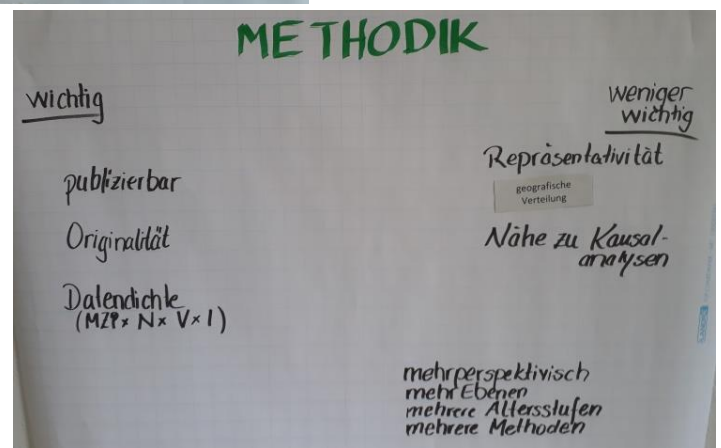

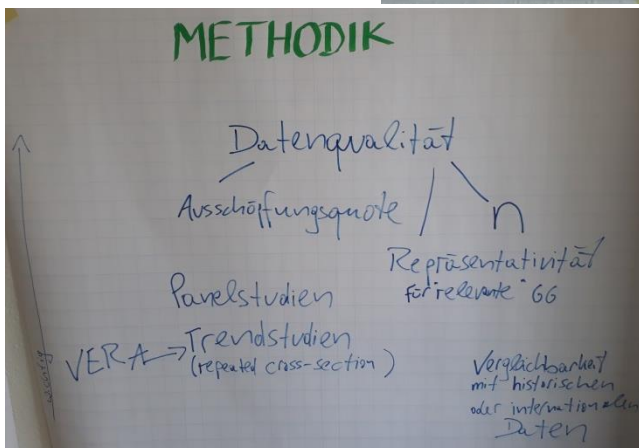

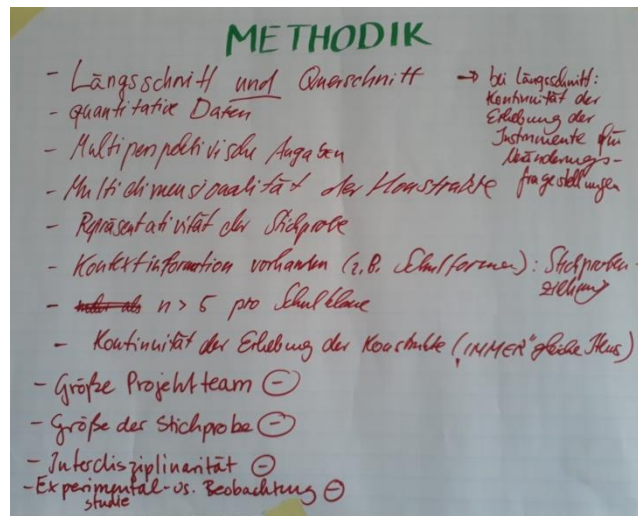

- Core data set/register
- Regional Identifier
- Thematic breadth --- Number of variables
- SES
- VERA
- IQB Trends in Student Achievement (Link GS-SEK I)

**Poster 3** (right side, top is most important, bottom least):

- Originality
- Data density/complexity
- Standardized instruments (connectable)
- Demography
- Regional information

Poster on the topic of methodology

Poster 1:

- Longitudinal section and cross-section -- for longitudinal section: continuity of the survey of instruments for change
- Quantitative data
- Multi-perspective tasks
- Multidimensionality of the constructs
- Representativeness of the sample
- Context information available (e.g. types of school): Sampling
- $n > 5$  per school class
- Continuity of the survey of constructs ("Always" same items)
- Size of project team -
- Size of the sample -
- Interdisciplinarity -
- Experimental vs. observational study -

**Poster 2** (left side, top is most important, bottom least):

- Data Quality
  - Response rate
  - Representativeness for "relevant" population
  - n
  
- Panel studies
- VERA --> Trend studies (repeated cross-section)
- Comparability with historical or international data

**Poster 3** (right side, top is most important, bottom least):

- Publishable
- Originality
- Data density (TxNxVxl)
  
- Representativeness
- Geographic distribution
- Proximity to causal analysis
  
- Multi-perspective
- More levels
- Several age groups
- Several methods
